

Link Layer (continued)

10Base5 (thick Ethernet) & 10Base2 (thin Ethernet)

FYI

Maximum 2500 meters with "repeaters" ("5-4-3" rule)

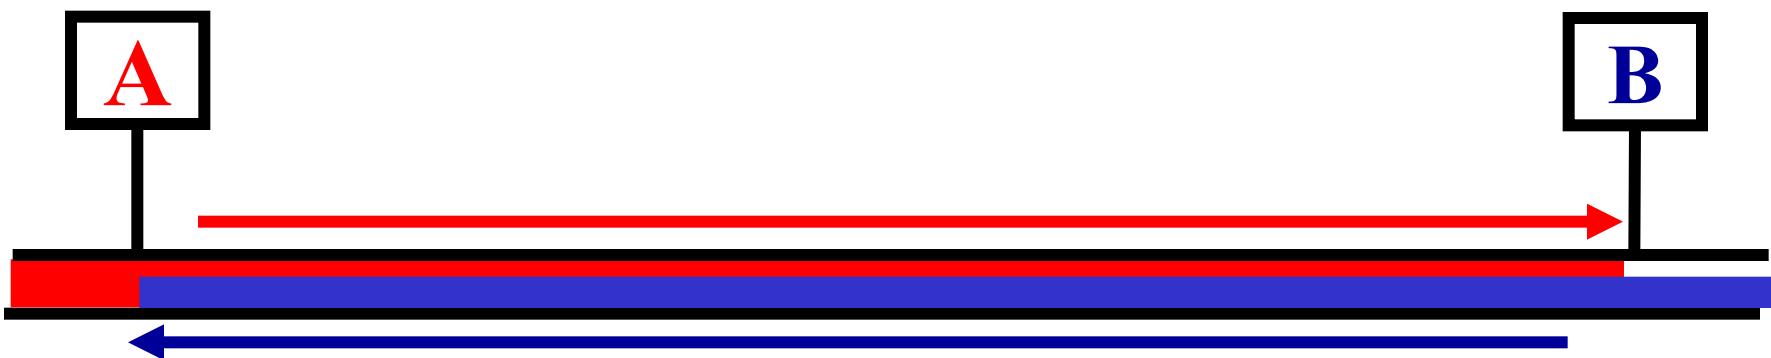

Maximum 185 meters without "repeaters"

Maximum 925 meters with "repeaters" ("5-4-3" rule)

Ethernet Frame Limits

- ◆ Upper limit on frames
 - Why?
 - To allow “fair” sharing of the shared bm
- ◆ Lower limit on frames
 - Why?
 - To reliably detect collisions
 - For 10Base5, cable max length 2500m → $2 * D_{\text{prop}} = 51.2 \mu\text{s}$
 - transceiver can send & listen at the same time; if received data stream differs from the one transmitted → collision
 - to detect collision: sender must be transmitting when garbled signal propagates back
 - minimum frame = 64bytes = 512bits, take 51μs to transmit at 10Mbps

Ethernet MAC protocol: CSMA/CD

A: sense channel, wait if necessary, when channel is idle, transmit and monitor the channel;

If detect collision

then {

abort and **send jam signal**;

update collision-count ($n++$);

delay for **K** slots (1 slot = 512bits transmission time)

goto A

}

else {finish sending the frame; reset collision-count ($n = 0$)}

Jam Signal (48 bits): make all other transmitters aware of collision

Exponential Backoff algorithm:

- ◆ first collision ($n=1$): choose **K** from {0, 1}
- ◆ second collision ($n =2$): choose **K** from {0, 1, 2, 3}...
- ◆ **after** 10 collisions ($n=10$), choose **K** from {0,1,2,3,4,...,1023}

CSMA/CD efficiency

- ◆ D_{prop} = max propagation delay between any 2 nodes
- ◆ D_{trans} = time to transmit a max-size frame

$$\text{efficiency} = \frac{1}{1 + 5D_{prop} / D_{trans}}$$

- ◆ Efficiency goes to 1
 - as D_{prop} goes to 0
 - as D_{trans} goes to infinity
- ◆ much better performance than ALOHA, and still decentralized and simple

Summary of MAC protocols

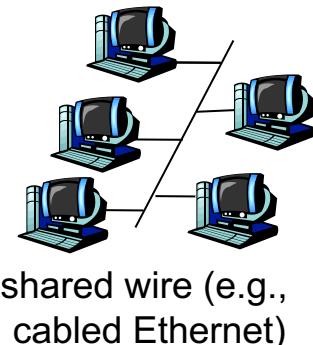

- ◆ Channel partitioning
 - Time Division (TDMA), Frequency Division (FDMA)
- ◆ Coordinated access (taking turns)
 - polling from central site or token passing
- ◆ Random access
 - ALOHA, S-ALOHA
 - CSMA: Carrier Sensing in MultiAccess: easy in some case (wire), harder in others (wireless)
 - CSMA/CD used in 10Base2, 10Base5 Ethernet
 - CSMA/CA used in 802.11 (WiFi)

Network Links

...

- ♦ In broadcast links one may want to
 - talk to everybody
 - talk to individual nodes
 - need some access control
- ♦ A set of point-to-point links can appear as broadcast
 - switched Ethernet

...

humans at a cocktail party
(shared air, acoustical)

Need addressing

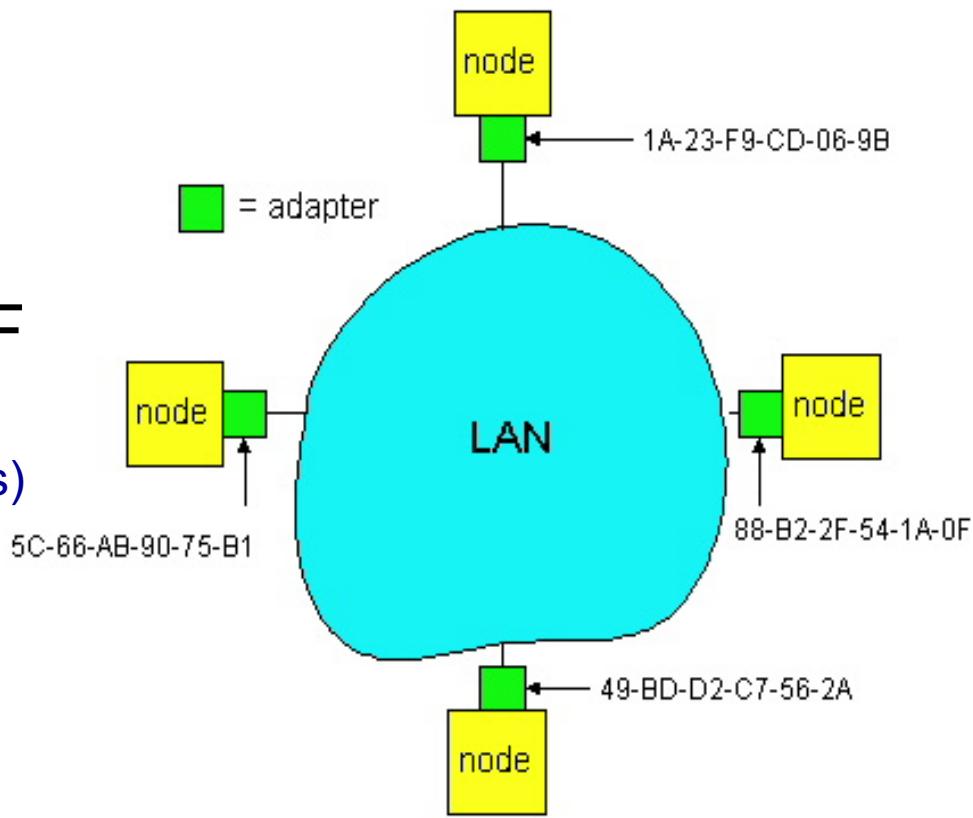

MAC Address (more)

- ◆ MAC address allocation by IEEE
- ◆ manufacturers buy MAC address blocks from IEEE
- ◆ MAC address is flat → portability
 - LAN card can move from one LAN to another
 - In comparison: IP address is hierarchical, NOT portable
 - Tied to the network a node is attached to
- ◆ Analogy:
 - MAC address: like Social Security Number
 - IP address: like postal address

MAC (or LAN or Ethernet) Address

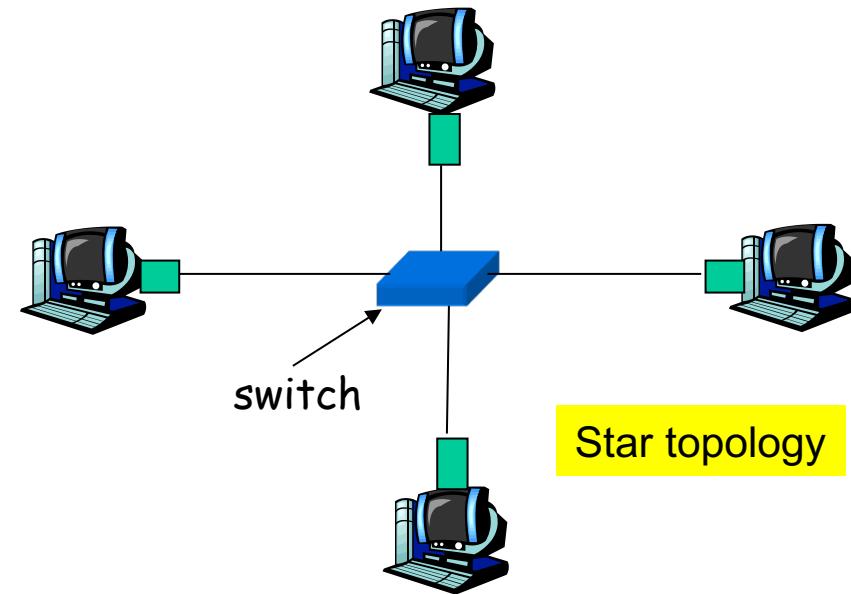

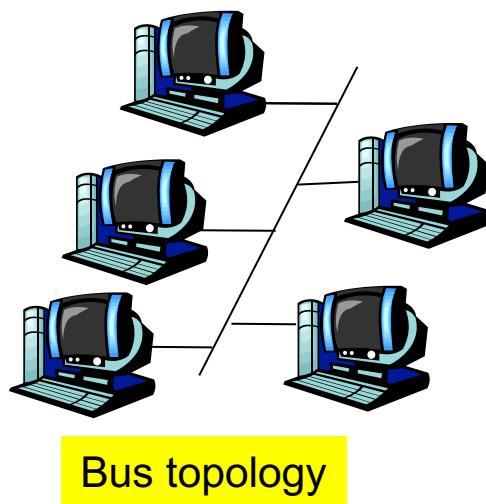

- ◆ 48 bit address, used to get data frame from one interface to another physically connected interface (on the same network)
- ◆ Each adapter on LAN has a unique LAN address
- ◆ Broadcast address:
FF-FF-FF-FF-FF-FF

hexadecimal (base 16) notation
(each “number” represents 4 bits)

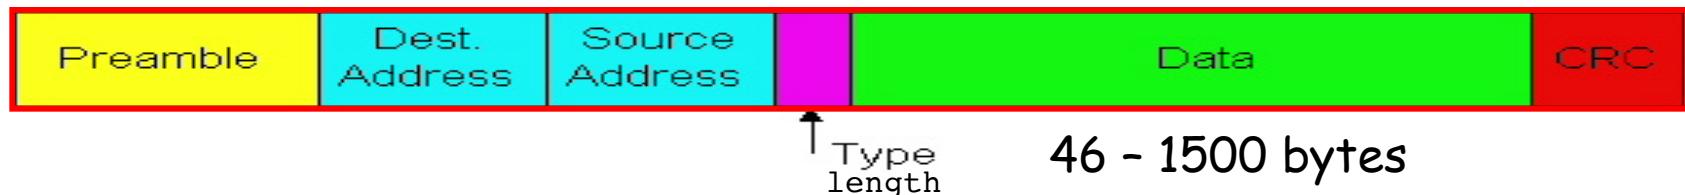

Ethernet

- ◆ Dominant LAN technology till wireless showed up
- ◆ Kept up with speed race: 10 Mbps – 100 Gbps
- ◆ Bus topology popular through mid 90s
- ◆ Switch-based star topology prevailed as speed goes up
 - Ethernet protocol runs on each wire

Ethernet Frame Structure

- ◆ Sending adapter encapsulates IP datagram in **Ethernet frame**
- ◆ **Preamble:** 8bytes
 - 7 bytes with pattern 10101010 followed by one byte with pattern 10101011
 - used to synchronize receiver, sender clock rates
- ◆ **Addresses:** 6 bytes each
 - If received frame destination address matches NIC address, or is broadcast address, the adapter passes data to network layer protocol; otherwise, discards frame
- ◆ **Type:** 2 bytes, indicates the higher layer protocol
 - IEEE802.3 changed the “type” field to “length”, defined a separate type field carried in the data part
- ◆ **CRC:** 4 bytes, added by sender, checked at receiver, if error, drop

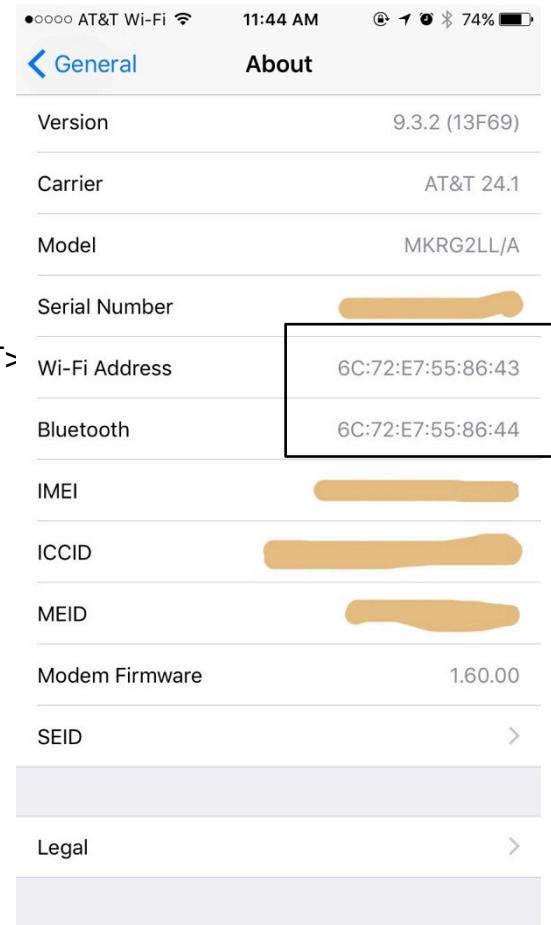

Ethernet: Unreliable data delivery

- ◆ connectionless: No handshaking between sending and receiving NICs
- ◆ unreliable: receiving NIC doesn't send acks or nacks to sending NIC
- ◆ Ethernet's MAC protocol: CSMA/CD
 - Does not concern with reliable delivery
 - *does concern with collision resolution*

Discovering MAC addresses

- ◆ Written on the device (sticker)
- ◆ ifconfig (Linux, OS X), ipconfig (Windows)
- ◆ Network interface settings

```
✓ 11:40 ~ $ ifconfig
en0: flags=8963<UP,BROADCAST,SMART,RUNNING,PROMISC,SIMPLEX,MULTICAST>
      mtu 1500
      ether 3c:15:c2:b8:b1:7e
      inet 169.254.145.207 netmask 0xfffff0000 broadcast
          169.254.255.255
          nd6 options=1<PERFORMNUD>
          media: autoselect
          status: active
en1: flags=963<UP,BROADCAST,SMART,RUNNING,PROMISC,SIMPLEX> mtu 1500
      options=60<TS04,TS06>
      ether 72:00:03:04:73:00
      media: autoselect <full-duplex>
      status: inactive
en2: flags=963<UP,BROADCAST,SMART,RUNNING,PROMISC,SIMPLEX> mtu 1500
      options=60<TS04,TS06>
      ether 72:00:03:04:73:01
      media: autoselect <full-duplex>
      status: inactive
```

Packet Delivery Dilemma

- ◆ Link layer uses MAC addresses to deliver packets to destinations
 - unique within LAN segment
- ◆ IP router knows only IP address of the destination?
 - globally unique*
- ◆ How to deliver packets?

Address Resolution Protocol (ARP)

- ◆ A knows B's IP address, wants to learn B's MAC address
- ◆ A *broadcasts* ARP query msg containing B's IP address
 - Dest. MAC address: FF-FF-FF-FF-FF-FF (broadcast)
 - all machines on LAN receive ARP query
- ◆ B receives ARP query, replies with B's MAC address
 - sent to A's MAC address (unicast)
- ◆ A caches B's [IP:MAC] address pairs until the information becomes too old

ARP Example with Wireshark

Wireshark capture window showing ARP traffic on interface Thunderbolt Ethernet: en3. Filtered for "arp".

No.	Time	Source	Destination	Protocol	Length	Info
212	12.478282	CiscoInc_52:4c:5b	Broadcast	ARP	60	Who has 131.179.196.236? Tell 131.179.196.3

- Address Resolution Protocol (reply)
 - Hardware type: Ethernet (1)
 - Protocol type: IPv4 (0x0800)
 - Hardware size: 6
 - Protocol size: 4
 - Opcode: reply (2)
 - Sender MAC address: Newisys_13:17:ff (00:09:3d:13:17:ff)
 - Sender IP address: 131.179.196.141
 - Target MAC address: Apple_c0:61:b6 (68:5b:35:c0:61:b6)
 - Target IP address: 131.179.196.220

ARP: plug-and-play

- ◆ Every IP node (Host, Router) on LAN keeps **ARP table**
- ◆ Each table entry: represents a node on the LAN:
< IP address; MAC address; TTL >
 - TTL (Time To Live): the entry's lifetime (typically 20 min)
 - One example of *soft-state* design: information deletes itself after certain time unless being refreshed

Nodes create their ARP tables without intervention from network administrator

Look Into Your ARP Table

✓ 12:06 ~ OSX \$ arp -an

? (131.179.196.1) at 0:0:c:7:ac:c4 on en3 ifscope [ethernet]

Administrators can also modify ARP entries, though not normally needed

Sending packets: IPA → IPB

- Find an entry in the routing table

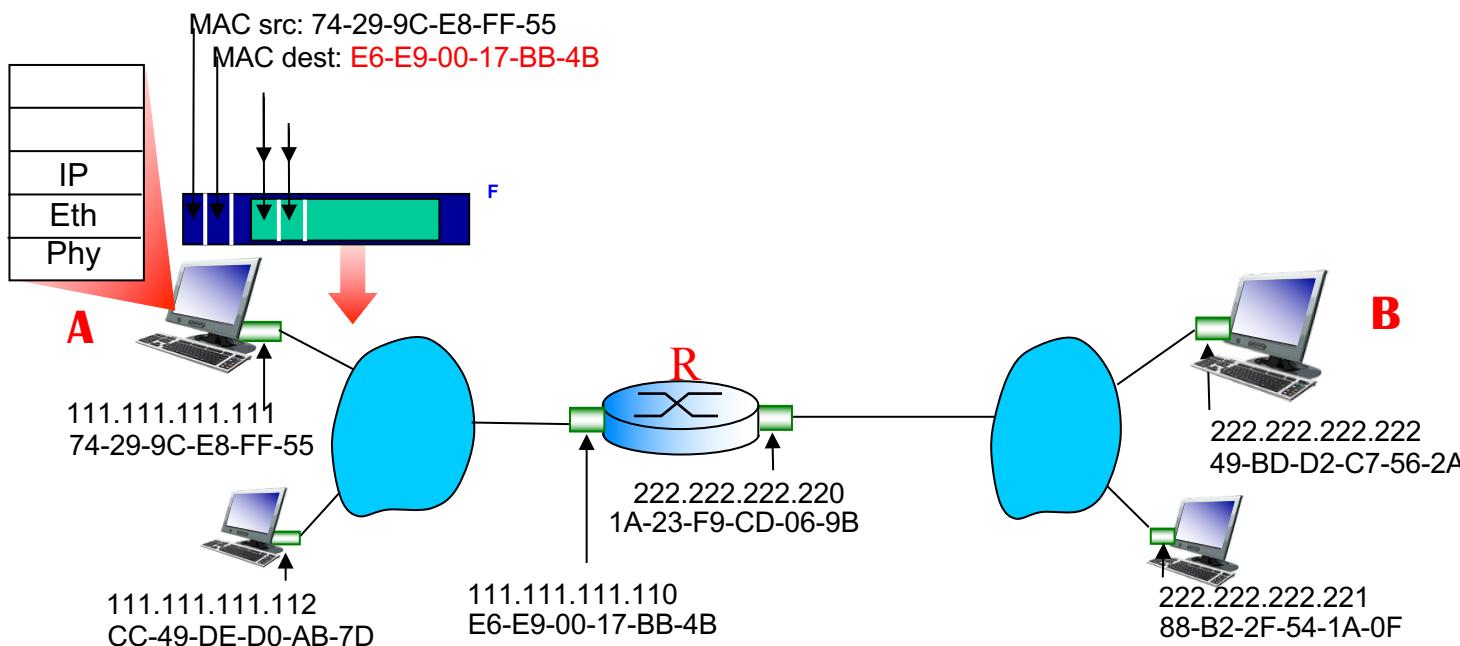

Destination	Gateway	Genmask	Flags	Metric	Ref	Use	Iface
131.179.196.0	0.0.0.0	255.255.255.0	U	0	0	0	br0

- If entry is saying that packet can be sent directly

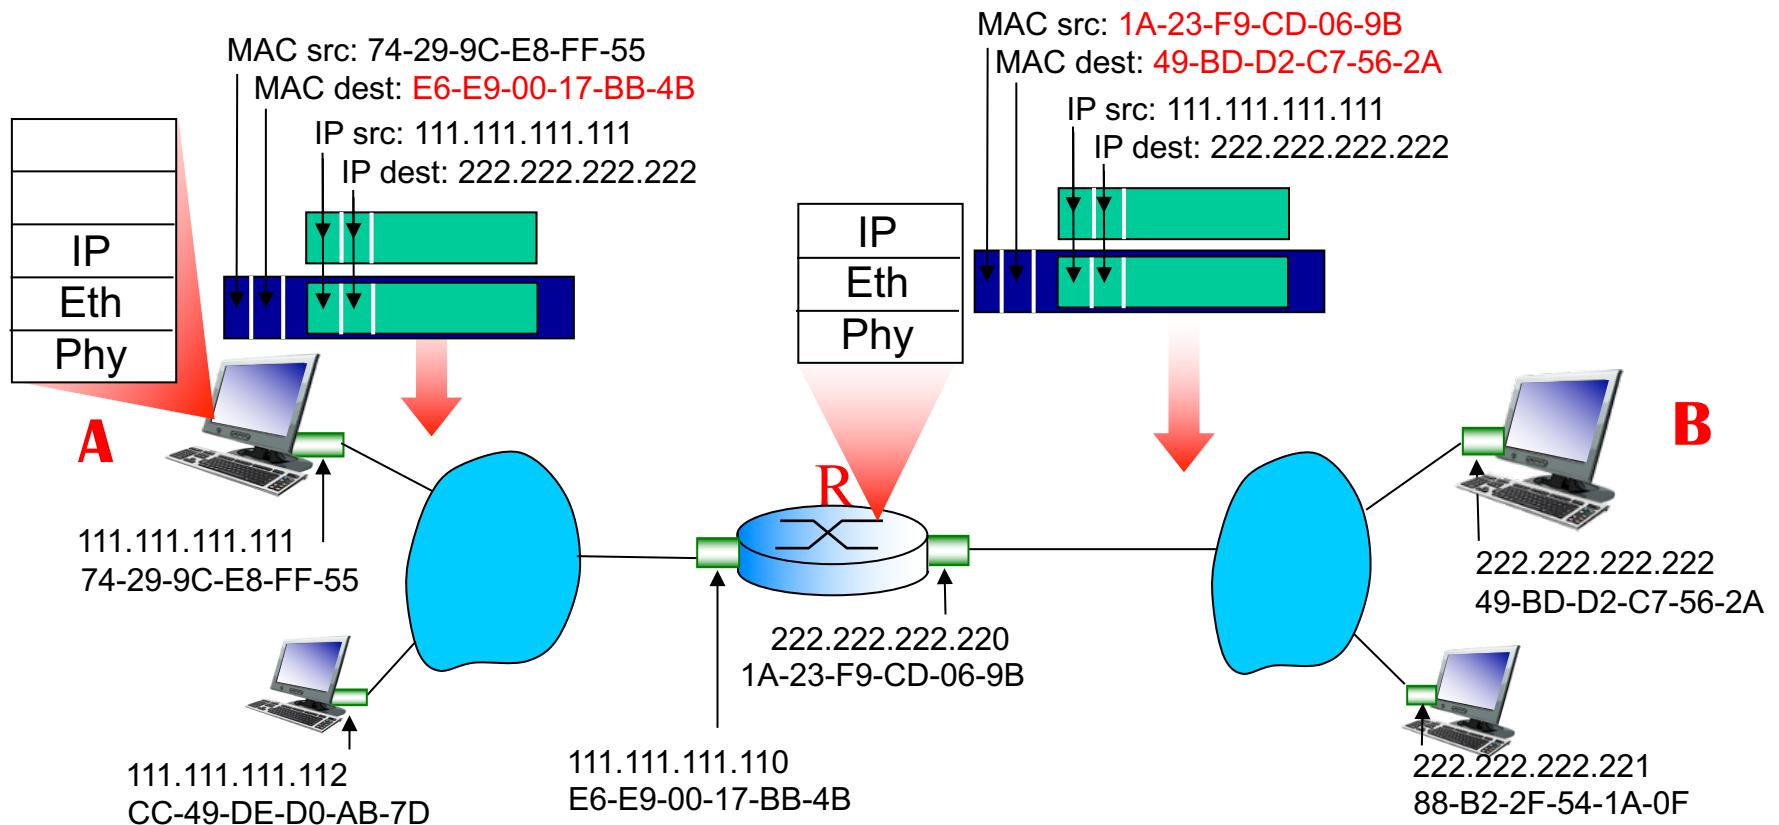

- Lookup MAC for destination IP (can be cached)

Destination	Gateway	Genmask	Flags	Metric	Ref	Use	Iface
0.0.0.0	131.179.196.1	0.0.0.0	UG	0	0	0	br0

- If entry is saying that packet should be set to the gateway
 - Lookup MAC for the gateway's IP
- Create frame with the found MAC and original IP packet as a payload
- Send the frame

- Router or node receives the frame, as it is destined to it
- Removes Ethernet header, finds IP destination address
- If IP is “self”, deliver to transport, which will deliver to the app
- If IP is not self and node is router, repeat the previous steps (lookup routing table, lookup ARP, ...)

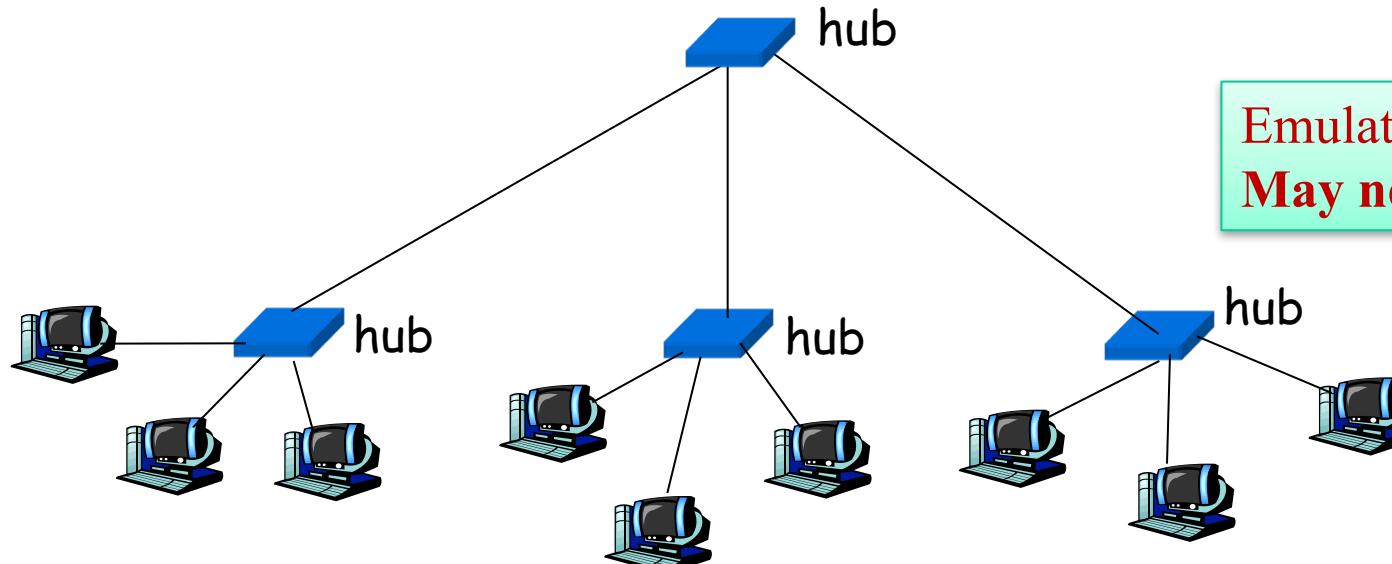

Ethernet Interconnection

Repeaters, Hubs, Switches

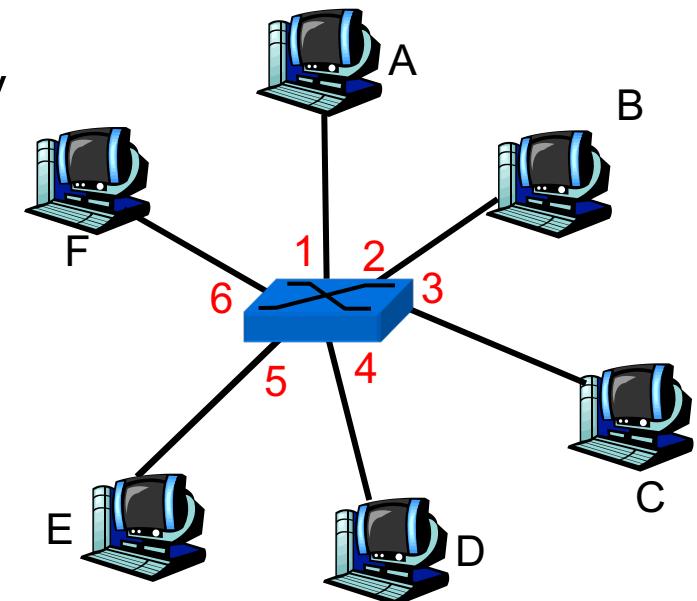

Ethernet Hub and Repeaters

- Repeating: physical layer devices
 - bits coming in one link go out all other links at same rate
- Hubs: link layer devices
 - packets coming in one port/link, go out all other ports/links
- Both
 - Extend max distance between nodes
 - Transmission by one node may collide with any node residing at any segment connected to the same hub
 - All pieces connected by one hub considered as one Ethernet

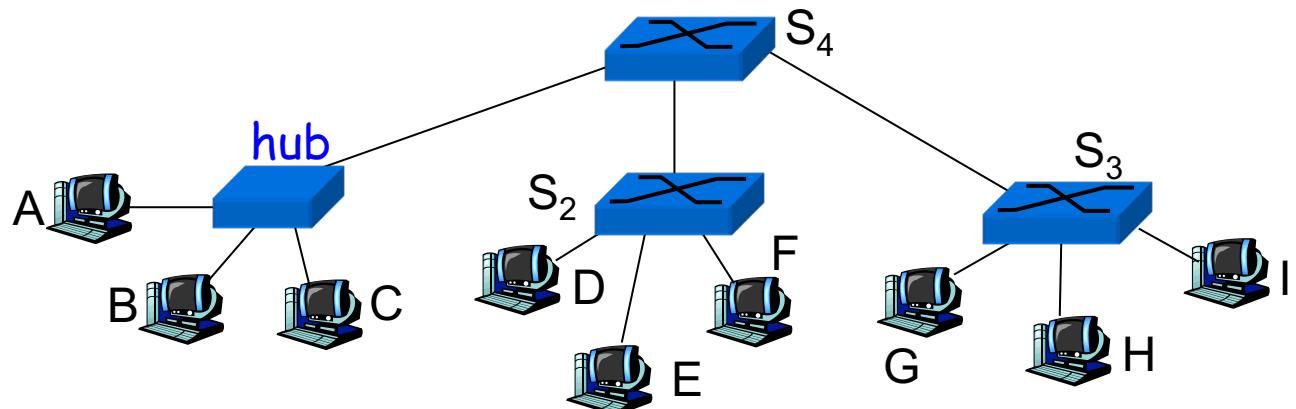

Ethernet Switch

- ◆ **Link layer device**: behave as a host on each connected LAN
 - speak Ethernet protocol at each interface
 - knows ARP protocol, but just listens and acts (no actively speaking)
 - transparent: hosts are unaware of presence of switches
- ◆ Store-and-forward: examine each incoming frame's MAC address, forward to the destination LAN if dest. host is on a different LAN
 - A→D and B→E can go simultaneously
 - buffer frames temporarily if next LAN busy
- ◆ **NO configuration needed**
 - Plug-and-play

Switches vs. hubs

- ◆ Bit forwarding vs store-and-forward devices
 - hub: pure signal amplification
 - e.g. if A sends a frame, S4 can hear it
 - switches: buffer then forward
 - e.g. if D sends a frame to E, S4 does not hear it
- ◆ Switch can connect different LANs

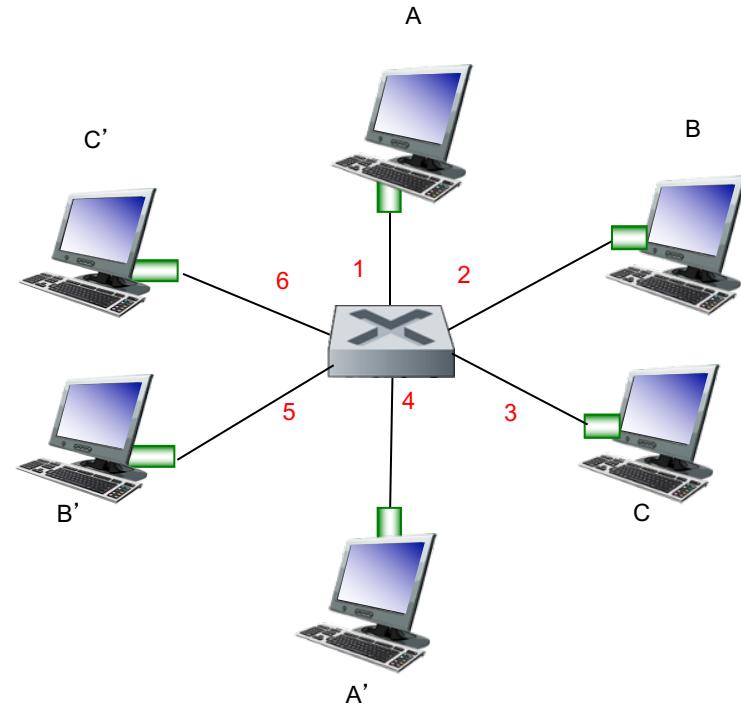

Switch needs a forwarding table

Q: how does switch know A is reachable via interface 4, B is reachable via interface 5?

- ❖ A: each switch has a **switch table**, each entry:
 - (MAC address of host, interface to reach host, time stamp)
 - looks like a routing table!

Q: how are entries created, maintained in switch table?

- something like a routing protocol?

An ethernet switch with 6 Interfaces (1,2,3,4,5,6)

Building a forwarding table by self-learning

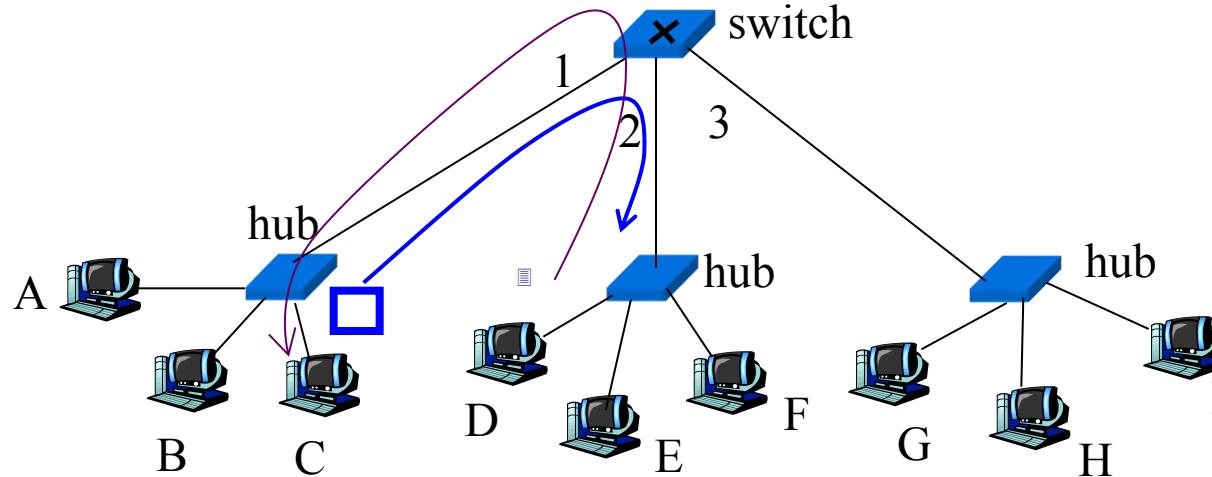

When receive data frame:

1. If not already in the table: record incoming link, MAC address of sending host
 - Each entry contains: MAC address, Interface, time stamp
 - stale entries are dropped (**TTL can be 60 min**)
2. switch table indexed by MAC destination address
3. if table entry found for destination
then {
 - if destination on segment from which frame arrived
then drop frame
 - else forward frame to interface indicated by entry
- }
else flood /* forward to all interfaces except the arriving interface */

important

Ethernet switch example

Suppose C sends a data frame  to D

address	interface
A	1
B	1
E	2
G	3
C	1
D	2

Switch receives frame  from C

Add to forwarding table: C is on interface 1

D is not in table: forwards  to interfaces 2 and 3

 is received by D

When D replies back with a frame  to C

Switch: Add to forwarding table: D is on interface 2

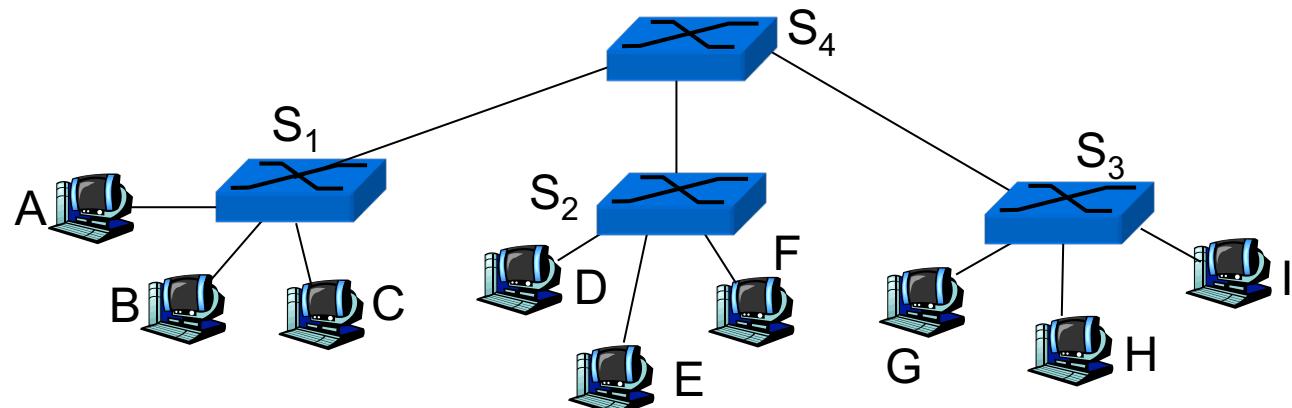

Forward  to C

Interconnecting switches

- ♦ Switches can be connected together

Q: sending from A to F -- how does S_1 know to forward frame destined to F via S_4 and S_2 ?

A: self learning! (works exactly the same as in single-switch case)

Self-learning switches: an example

- ◆ Consider the following frame transmission:

$A \rightarrow B, B \rightarrow A$

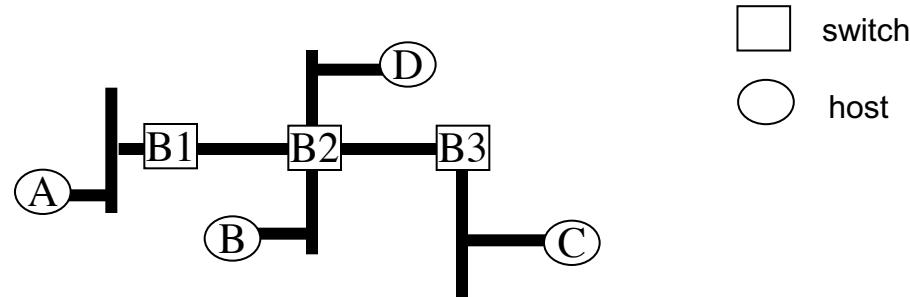

$B \rightarrow C, C \rightarrow B$

$D \rightarrow C, C \rightarrow D$

Q: How many times does B2 need to flood the data frame?

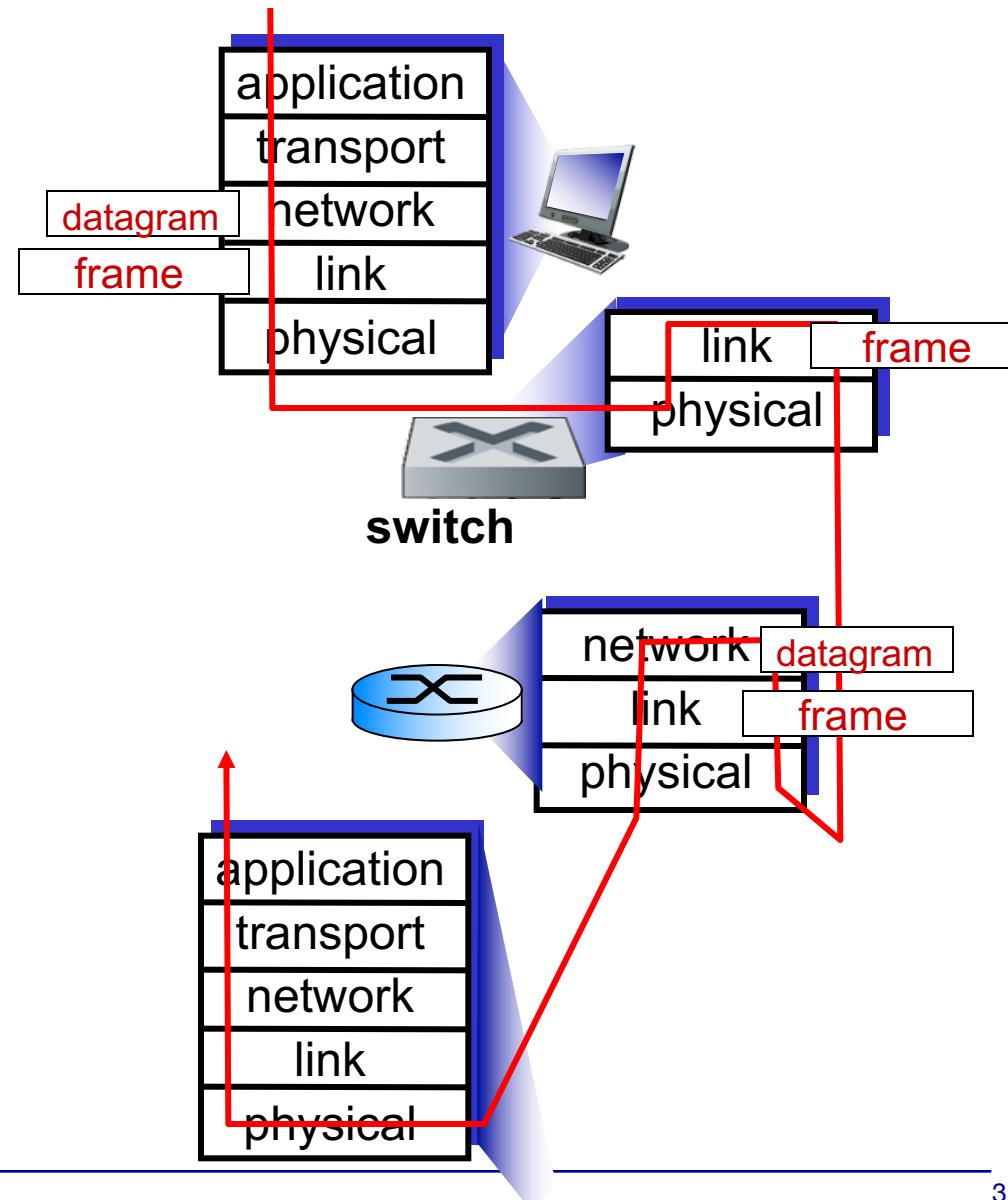

$A \rightarrow B$: B2 flood

$B \rightarrow C$: B2 flood

Switches vs. Routers

- both are store-and-forward devices
 - routers: network layer devices (examine IP headers)
 - Switches: link layer devices (examine Ethernet headers)
- Build forwarding table
 - routers run routing protocols
 - switches implement self-learning algorithms

Switches: advantages and limitations

- ◆ Transparent: no change to hosts
- ◆ Isolates collision domains
 - resulting in higher total maximum throughput
- ◆ Can connect Ethernets of different speeds
 - because it is a store and forward device
- ◆ Constrained topology: ***tree only***
 - all inter-segment traffic concentrated on a single tree
 - (all multicast traffic forwarded to all LAN's)

Routers: advantages and limitations

- ◆ Support arbitrary topologies
- ◆ Efficient support for multicast routing
- ◆ Require IP address configuration (not plug-and-play)
- ◆ More complex packet processing than switches
- ◆ Switches do well in small setting, routers are used in large networks

Q: what is in a routing table, an ARP table, and a switch's forwarding table?

Interconnecting LANs

Q: Why not just one big LAN?

- Signal attenuation; limited physical distance
- all stations on one LAN share bandwidth → limited total throughput
- ◆ A number of different types of “connectors”
 - router (already mentioned, L3)
 - bridge, Ethernet switch (L2)
 - Frame forwarding
 - Perform CSMA/CD
 - repeater, hub (L1)
 - bit level forwarding
 - Signal amplification
